Lecture 12: Analytical examples of Bayesian inference

Professor Ilias Bilionis

Decision making

The Decision-making problem

- What if someone asks you to report a single value for θ in the coin toss example?
- What is the correct way of doing this?
- To answer it, you have to quantify the cost of making a mistake and then make a decision that minimizes this cost.

The Decision-making problem

• The **loss** when we guess $\underline{\theta}'$ and the true value is $\underline{\theta} = \ell(\theta', \theta)$

$$F[l(9',9)|x_1:n] = \begin{cases} l(9',9) & p(9|x_1:n) & d9 \\ loss & cond. \end{cases}$$
win $F[l(9',9)|x_1:n]$

win $F[l(9',9)|x_1:n]$

The 0-1 Loss

$$\mathcal{E}_{01}(\theta',\theta) = \begin{cases} 0, & \theta' = 9 \\ 1, & \theta' \neq \theta \end{cases}$$

$$\mathcal{E}_{01}(\theta',\theta) = \begin{cases} 0, & \theta' = 9 \\ 1, & \theta' \neq \theta \end{cases}$$

$$\mathcal{E}_{01}(\theta',\theta) = \begin{cases} 0, & \theta' = 9 \\ 1, & \theta' \neq \theta \end{cases}$$

$$\mathcal{E}_{01}(\theta',\theta) = \begin{cases} 0, & \theta' = 9 \\ 1, & \theta' \neq \theta \end{cases}$$

$$\mathcal{E}_{01}(\theta',\theta) = \begin{cases} 0, & \theta' = \theta \\ 1, & \theta' \neq \theta \end{cases}$$

$$\mathcal{E}_{01}(\theta',\theta) = \begin{cases} 0, & \theta' \neq \theta \\ 1, & \theta' \neq \theta \end{cases}$$

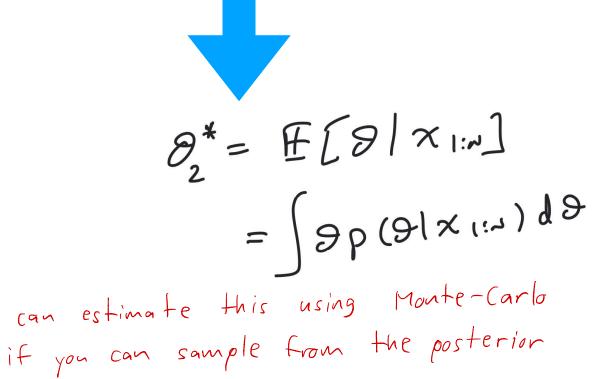

$$\mathcal{E}_{01}(\theta',\theta) = \begin{cases} 0, & \theta' \neq \theta \\ 1, & \theta' \neq \theta \end{cases}$$

$$\mathcal{E}_{01}(\theta',\theta) = \begin{cases} 0, & \theta' \neq \theta \\ 1, & \theta' \neq \theta \end{cases}$$

The Square Loss

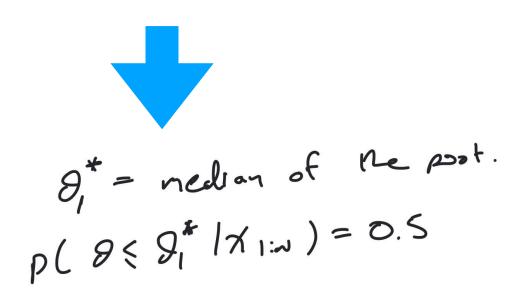

$$\mathcal{C}_2(\theta',\theta) = (\theta' - \theta)^2$$

The Absolute Loss

$$\mathcal{E}_{\mathbf{1}}(\theta',\theta) = |\underline{\theta}' - \underline{\theta}|$$

Example: Coin toss - Picking a value

Using the square loss, we get:

$$9_{\lambda}^{*} = \frac{1 + \frac{2}{2} \times i}{N + 2}$$

stems from the expectation of a Beta distribution
